Problem Set 2

Due: May 3, 2021 (in class; subject to change if COVID restrictions apply)

A binary response is a variable that takes on only two values, customarily 0 and 1, which can be thought of as codes for whether or not a condisiton is satisfied. For example, 0=drive to work, 1=take the bus. Often the observed binary variable, say y, is related to an unobserved (latent) continuous variable, say y^* . We would like to know the effect of covariates, x, on y. The model can be represented as

$$egin{aligned} y^* &= g(x) - arepsilon \ y &= 1(y^* > 0) \ Pr(y &= 1) &= F_arepsilon[g(x)] \ &\equiv p(x, heta) \end{aligned}$$

For the logit model, the probability has the specific form

$$p(x, heta) = rac{1}{1 + \exp(-x' heta)}$$

Problem 1 (MLE)

We will consider maximum likelihood estimation of the logit model for binary 0/1 dependent variables. We will use the BFGS algorithm to find the MLE.

The log-likelihood function is

$$s_n(heta) = rac{1}{n} \sum_{i=1}^n \left(y_i \ln p(x_i, heta) + (1-y_i) \ln [1-p(x_i, heta)]
ight)$$

The following code generates that follow a logit model with given θ :

```
In [4]: function LogitDGP(n, theta)
    k = size(theta,1)
    x = ones(n,1)
    if k>1
        x = [x randn(n,k-1)]
    end
    y = Float64.((1.0 ./ (1.0 .+ exp.(-x*theta)) .> rand(n,1)))
```

```
return y, x end
```

Out[4]: LogitDGP (generic function with 1 method)

Let us estimate $\hat{\theta}$ from the dataset with 100 points (n=100) and generated from the true θ (θ_0) value of [0.5,0.5].

Out[10]: ([1.0; 0.0; ...; 1.0; 0.0], [1.0 0.278557437317092; 1.0 0.09507474449420693; ...; 1.0 -0.9 180350890683213; 1.0 -0.16918013820719])

(1. a) Estimate $\hat{\theta}$.

Hint:

- 1. Refer to Nerlove lecture notes for an example code for mle estimation.
- 2. Code for the log likelihood function

$$s_n(heta) = rac{1}{n} \sum_{i=1}^n \left(y_i \ln p(x_i, heta) + (1-y_i) \ln [1-p(x_i, heta)]
ight)$$

is written as below:

(1. b) Empirically prove consistency of $\hat{\theta}$ by increasing the number of n in DGP and reestimate.

Hint: Refer to GMM lecture notes for an example code for empirically proving consistency.

(1. c) Empirically prove asymptotic normality of $\hat{ heta}$ by repeatedly generate data.

Hint: Refer to GMM lecture notes for an example code for empirically proving asymptotic normality.

Problem 2 (GMM)

Recall from GMM lecture notes:

Suppose the model is

$$y_t^* = \alpha + \rho y_{t-1}^* + \beta x_t + \epsilon_t \ y_t = y_t^* + v_t$$

where ϵ_t and v_t are independent Gaussian white noise errors. Suppose that y_t^* is not observed, and instead we observe y_t . If we estimate the equation

$$y_t = \alpha + \rho y_{t-1} + \beta x_t + \nu_t$$

this the estimator is biased and inconsistent.

What about using the GIV estimator?

Consider using as instruments $Z=[1\,x_t\,x_{t-1}\,x_{t-2}]$. The lags of x_t are correlated with y_{t-1} as long as β is different from zero, and by assumption x_t and its lags are uncorrelated with ϵ_t and v_t (and thus they're also uncorrelated with ν_t). Thus, these are legitimate instruments. As we have 4 instruments and 3 parameters, this is an overidentified situation.

```
In [238...
          function lag(x::Array{Float64,2},p::Int64)
                  n,k = size(x)
                   lagged_x = [ones(p,k); x[1:n-p,:]]
          end
          function lag(x::Array{Float64,1},p::Int64)
                  n = size(x,1)
                   lagged_x = [ones(p); x[1:n-p]]
          end
          function lags(x::Array{Float64,2},p)
                  n, k = size(x)
                   lagged_x = zeros(eltype(x),n,p*k)
                   for i = 1:p
                           lagged_x[:,i*k-k+1:i*k] = lag(x,i)
                   end
              return lagged_x
          end
          function lags(x::Array{Float64,1},p)
                  n = size(x,1)
                  lagged_x = zeros(eltype(x), n,p)
                   for i = 1:p
                           lagged x[:,i] = lag(x,i)
                   end
              return lagged_x
          end
```

Out[238... lags (generic function with 2 methods)

Given $[\alpha_0, \rho_0, \beta_0] = [0, 0.9, 1]$, let us generate data using the pre-defined lag function above:

(2. a) Given the following GIVmoments function, write down the moment conditions for each data point. In other words, write down $m_t(\theta)$ $\forall t$ where t is an index for each data points and $\overline{m}_n(\theta)$.

```
In [281...
          # moment condition
          function GIVmoments(theta, data)
                   data = [data lags(data,2)]
               data = data[3:end,:] # get rid of missings
                   n = size(data,1)
                   y = data[:,1]
                   ylag = data[:,2]
                   x = data[:,3]
                   xlag = data[:,6]
                   xlag2 = data[:,9]
                   X = [ones(n,1) ylag x]
                   e = y - X*theta
                   Z = [ones(n,1) \times xlag xlag2]
                   m = e.*Z
           end
```

Out[281... GIVmoments (generic function with 1 method)

(2. b) Calculate $\hat{\theta}$ using two step GMM.

Compare the estimates with the true parameter value: $[lpha_0,
ho_0,eta_0]=[0,0.9,1]$

Problem 3 (Nerlove)

Recall the Nerlove model from the previous lecture.

We have explored the property of HOD1 (homogeneous degree 1):

$$\sum_{i=1}^g \beta_i = 1$$

In other words, the cost shares add up to 1.

Now, let's explore the property of CRTS (constant returns to scale):

$$\gamma = rac{1}{eta_q} = 1$$

so $\beta_q = 1$.

Let us first load the Nerlove data and log:

```
In [3]: data = DataFrame(CSV.File("../data/nerlove.csv"))
   data = log.(data[:,[:cost,:output,:labor,:fuel,:capital]])
   first(data,6)
```

 $Out[3]: 6 rows \times 5 columns$

```
cost output labor fuel capital
Float64 Float64 Float64 Float64
```

	cost	output	labor	fuel	capital
	Float64	Float64	Float64	Float64	Float64
1	-2.50104	0.693147	0.737164	2.8848	5.20949
2	-0.414001	1.09861	0.71784	3.5582	5.15906
3	-0.0100503	1.38629	0.71784	3.5582	5.14166
4	-1.15518	1.38629	0.604316	3.47197	5.11199
5	-1.62455	1.60944	0.751416	3.35341	5.45104
6	-2.32279	2.19722	0.751416	3.35341	5.273

Then, assign y and x values

```
In [5]:    n = size(data,1)
    y = data[:,1]
    x = data[:,2:end]
    x[!,:intercept]=ones(size(data,1))
    x = x[!,[:intercept,:output,:labor,:fuel,:capital]];

y = convert(Array,y)
    x = convert(Array,x);
```

- 3 (a). Estimate the parameters using Restricted OLS using the CRTS restrictions
- 3 (b). Calculate Wald, LR, and LM statistics and comment on the hypothesis test on restrictions.
